

5.0 BLUE RIVER BASINS

5.1 Summary

Based on the analysis of the sufficiency of the long-term surface water supply in the Blue River Basins, the Department has reached a preliminary conclusion that the basins are not fully appropriated. The Department has also determined that, if no additional legal constraints are imposed on future development of hydrologically connected surface water and groundwater and reasonable projections are made about the extent and location of future development, this preliminary conclusion would not change to a conclusion that the basin is fully appropriated, based on current information.

The analysis of lag effects of current development for areas in the western portion of the Big Blue River Basin indicates a reduction in streamflows by 34 cfs in twenty-five years. The analysis of lag effects of current development for areas in the western portion of the Little Blue River Basin indicates a reduction in streamflows by 25 cfs in twenty-five years. It was not possible to calculate lag effects of current development for areas in the eastern portions of the basins at this time due to the glaciated nature of the area and the fact that the principal aquifer is absent or very thin (CSD, 2005).

The analysis of the impacts of potential future development in the western portion of the Big Blue River Basin, based on current development trends, indicates an additional reduction in streamflows of 4 cfs in twenty-five years. The analysis of the impacts of potential future development in the western portion of the Little Blue River Basin based on current development trends indicates an additional reduction in streamflows of 14 cfs in twenty-five years. The potential impacts of future development in the eastern portions of the basins were not evaluated at this time due to the glaciated nature of the area and the fact that the principal aquifer is absent or very thin (CSD, 2005).

5.2 Basin Descriptions

The Blue River Basins in Nebraska include all surface areas that drain into the Big Blue River and the Little Blue River, and all aquifers that impact surface water flows of the basins

(figure 5-1). The total area of the Blue River surface water basins in Nebraska is approximately 7,100 square miles, of which 4,600 square miles are in the Big Blue River Basin and 2,500 square miles are in the Little Blue River Basin. NRDs with significant area in the basins are the Little Blue, the Lower Big Blue, the Upper Big Blue, and the Tri-Basin NRDs. The basins are the subject to an interstate compact between Kansas and Nebraska that sets state line target flows.

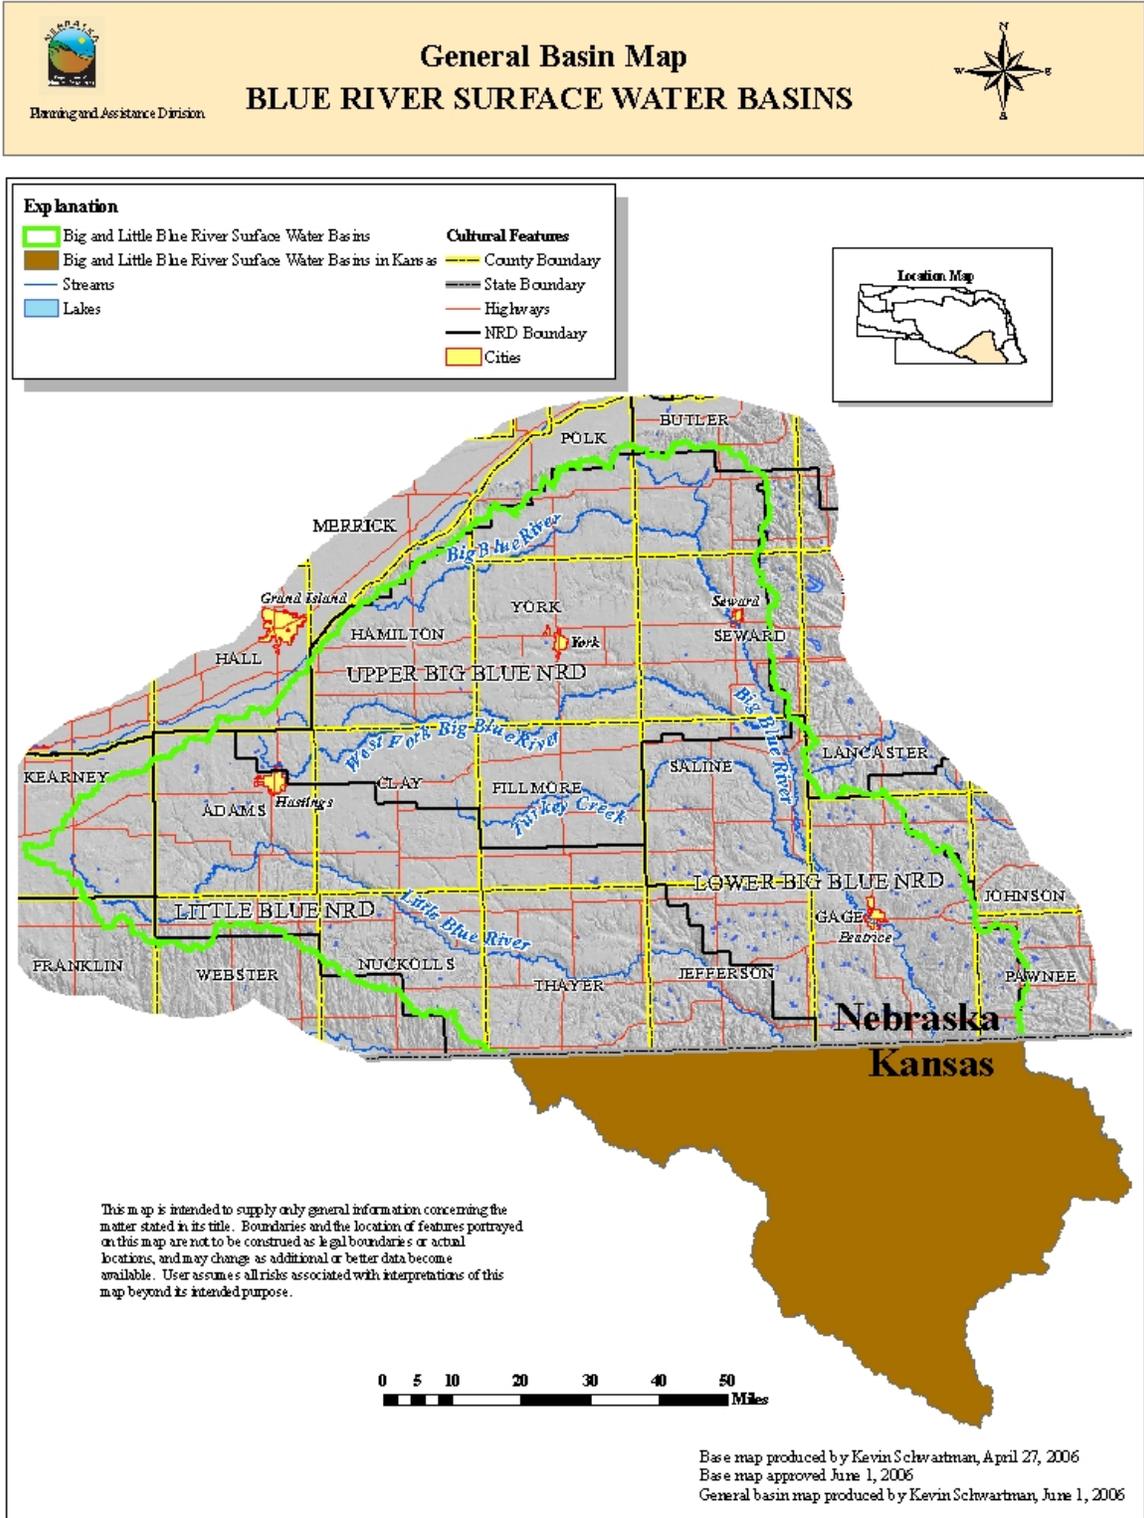

Figure 5-1. General basin map, Blue River Basins.

5.3 Nature and Extent of Water Use

5.3.1 Groundwater

Groundwater in the basins is used for a variety of purposes: domestic, industrial, livestock, irrigation, and other uses. A total of 25,568 groundwater wells had been registered within the basins as of December 31, 2009 (Department registered groundwater wells database) (figure 5-2). The locations of all active groundwater wells are shown in figure 5-3.

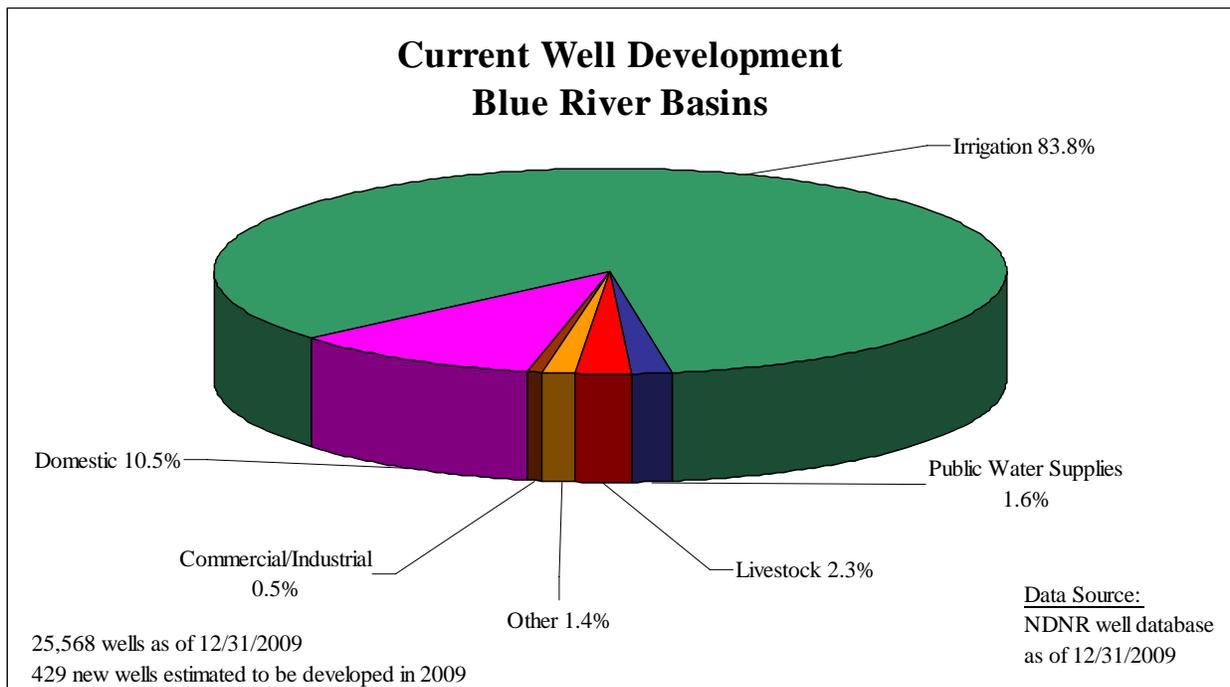

Figure 5-2. Current well development by number of registered wells, Blue River Basins.

Planning and Assistance Division

Current Well Development BLUE RIVER SURFACE WATER BASINS

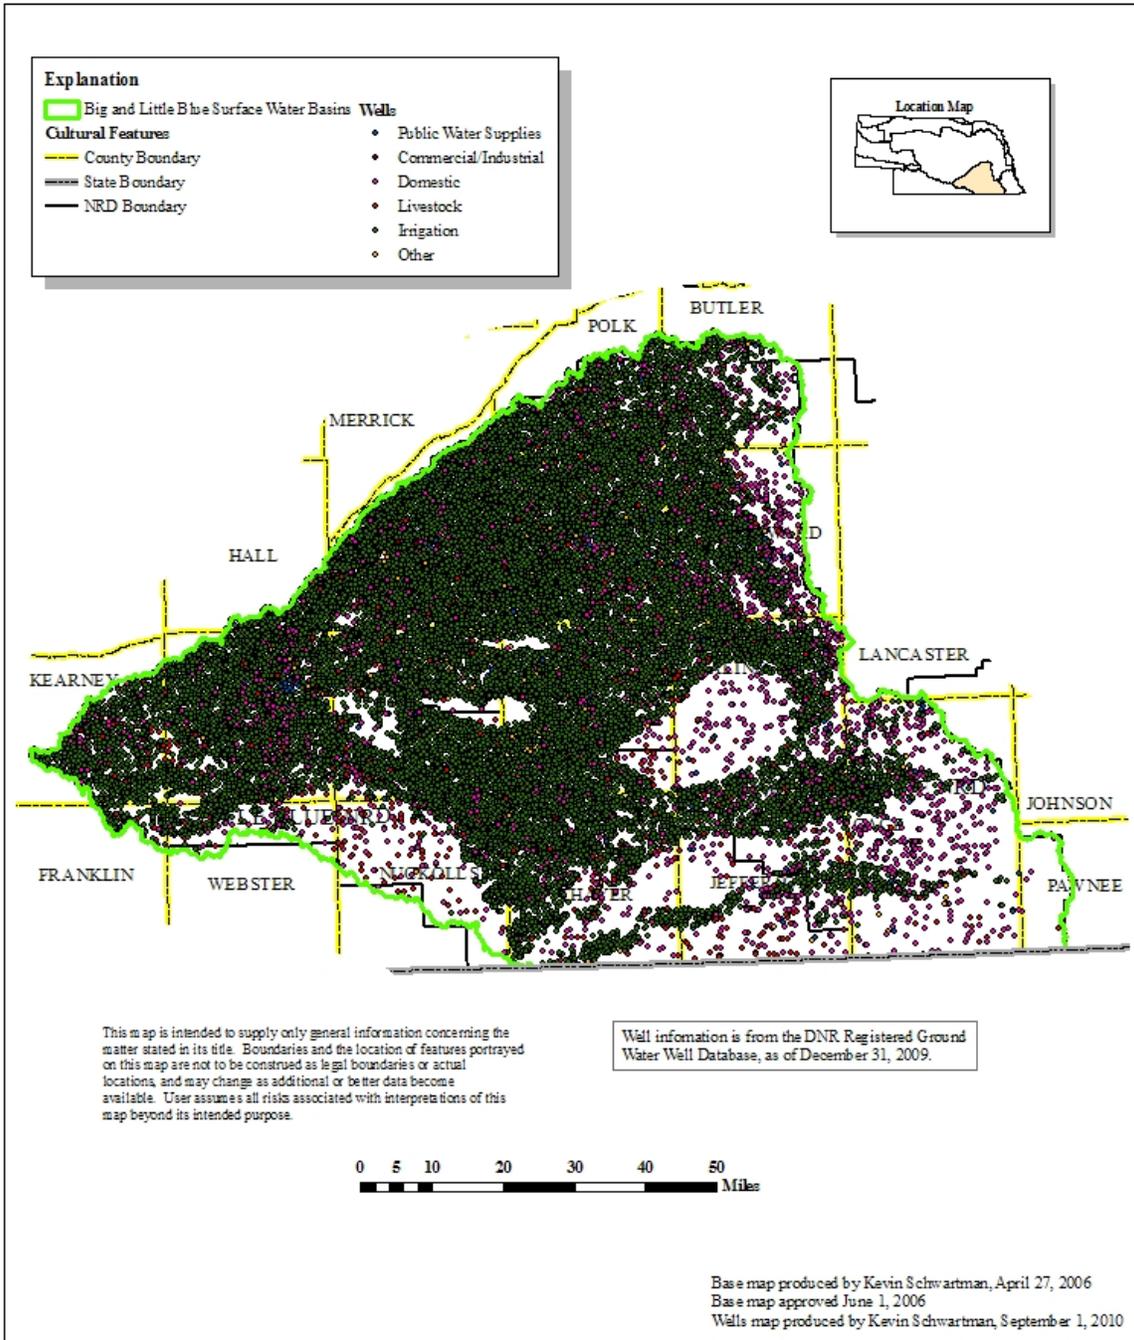

Figure 5-3. Current well locations, Blue River Basins.

5.3.2 Surface Water

As of December 31, 2009, 2,313 active surface water appropriations were held in the basins, issued for a variety of uses (figure 5-4). Most of the surface water appropriations are irrigation and storage uses that tend to be located on the major streams. The first surface water appropriations in the basins were permitted in 1868, and development has continued through the present day. The approximate locations of the surface water diversion points are shown in figure 5-5.

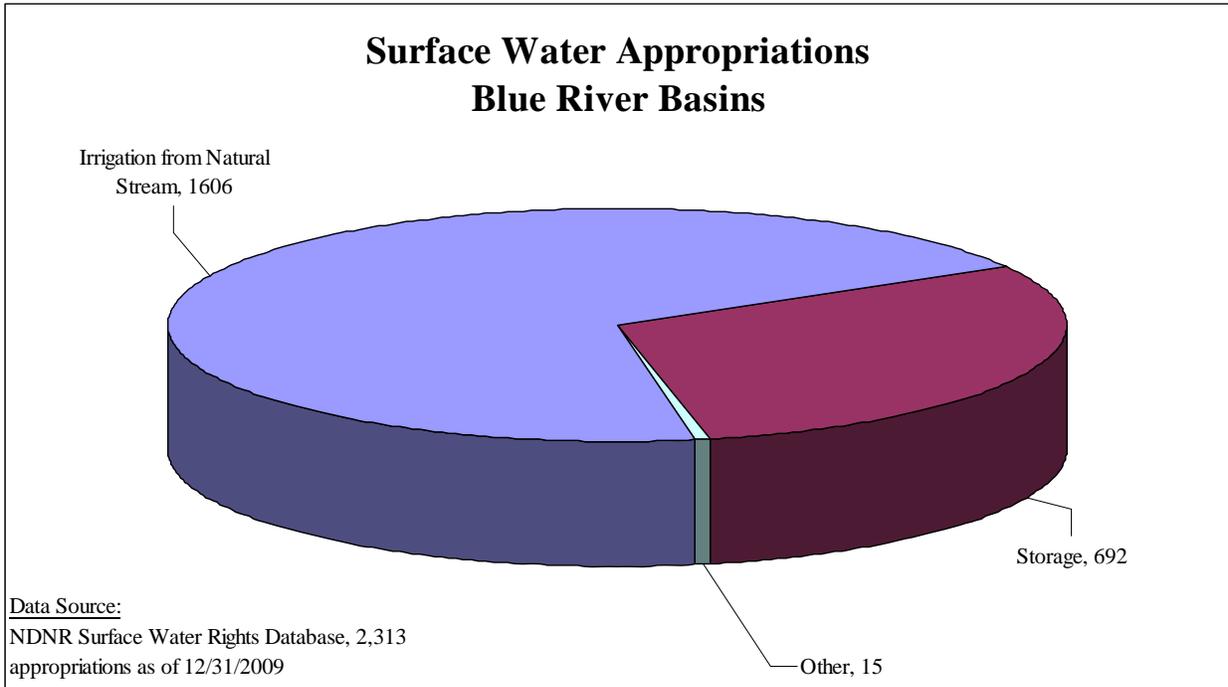

Figure 5-4. Surface water appropriations by number of diversion points, Blue River Basins.

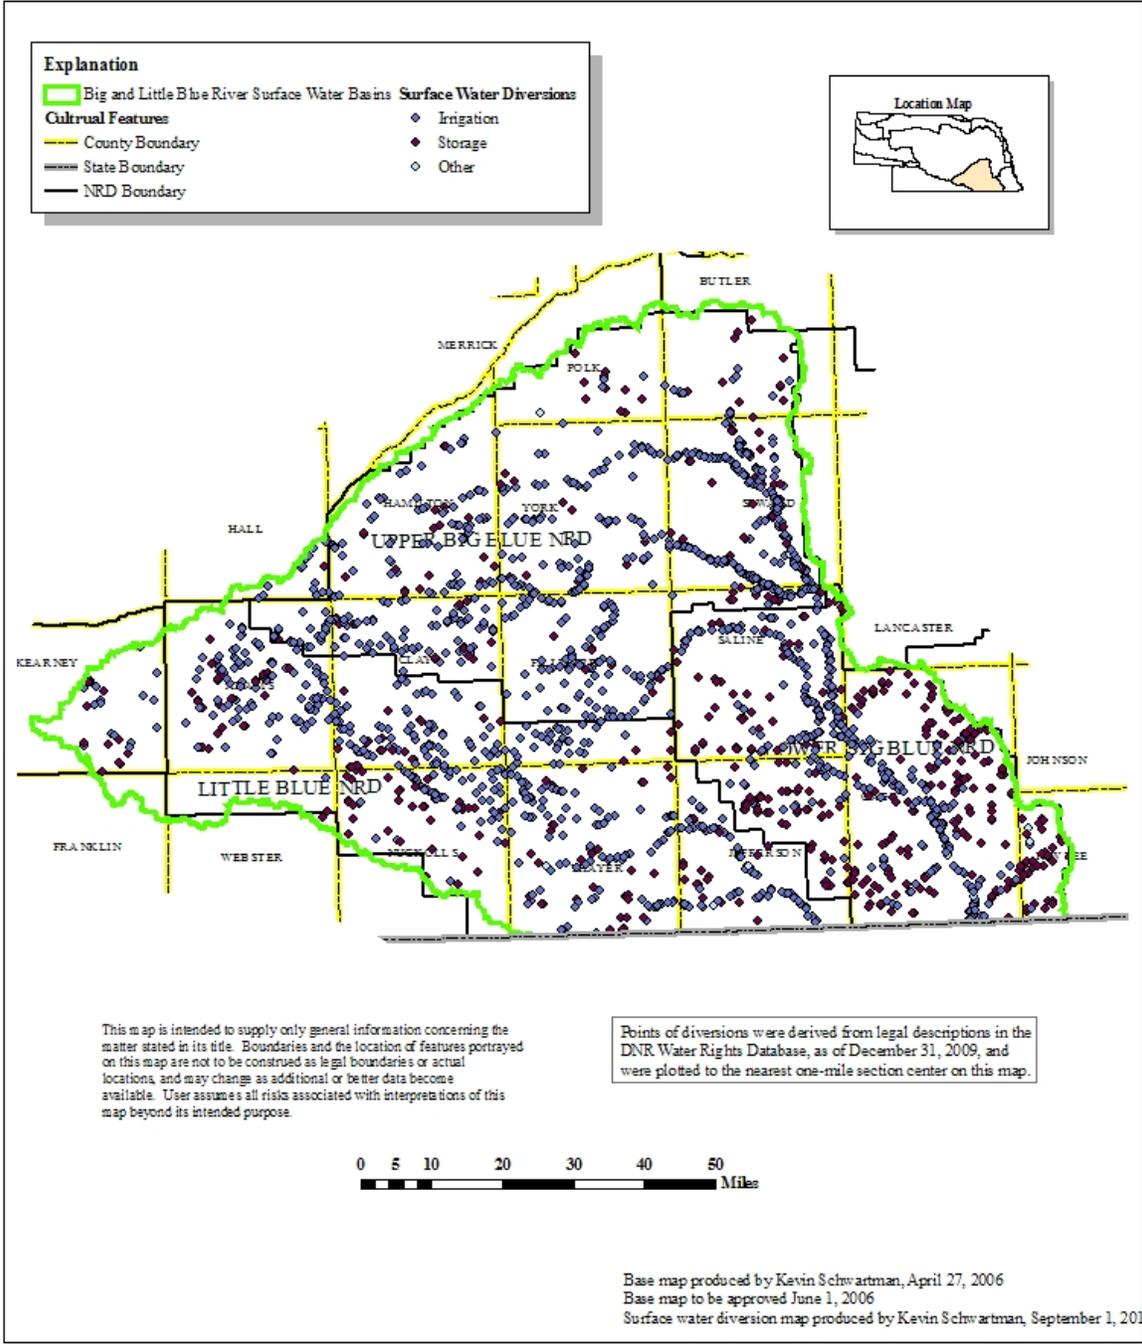

Figure 5-5. Surface water appropriation diversion locations, Blue River Basins.

5.4 Hydrologically Connected Area

The Blue River Basins can be divided into two distinct areas based on the presence or absence of glacial deposits. At the present time, the Department only has sufficient data to determine the 10/50 area for the Big Blue River and Little Blue River Basins in the western (non-glaciated) portion of the basins. Although a numeric groundwater model has been developed for the area and the results were previously utilized by the Department, reviews by the Department have deemed this model inappropriate for use at this time. Therefore, the 10/50 area was determined using the Hunt methodology (Hunt, 1999). Figure 5-6 specifies the extent of the 10/50 area for the western portion of the basin.

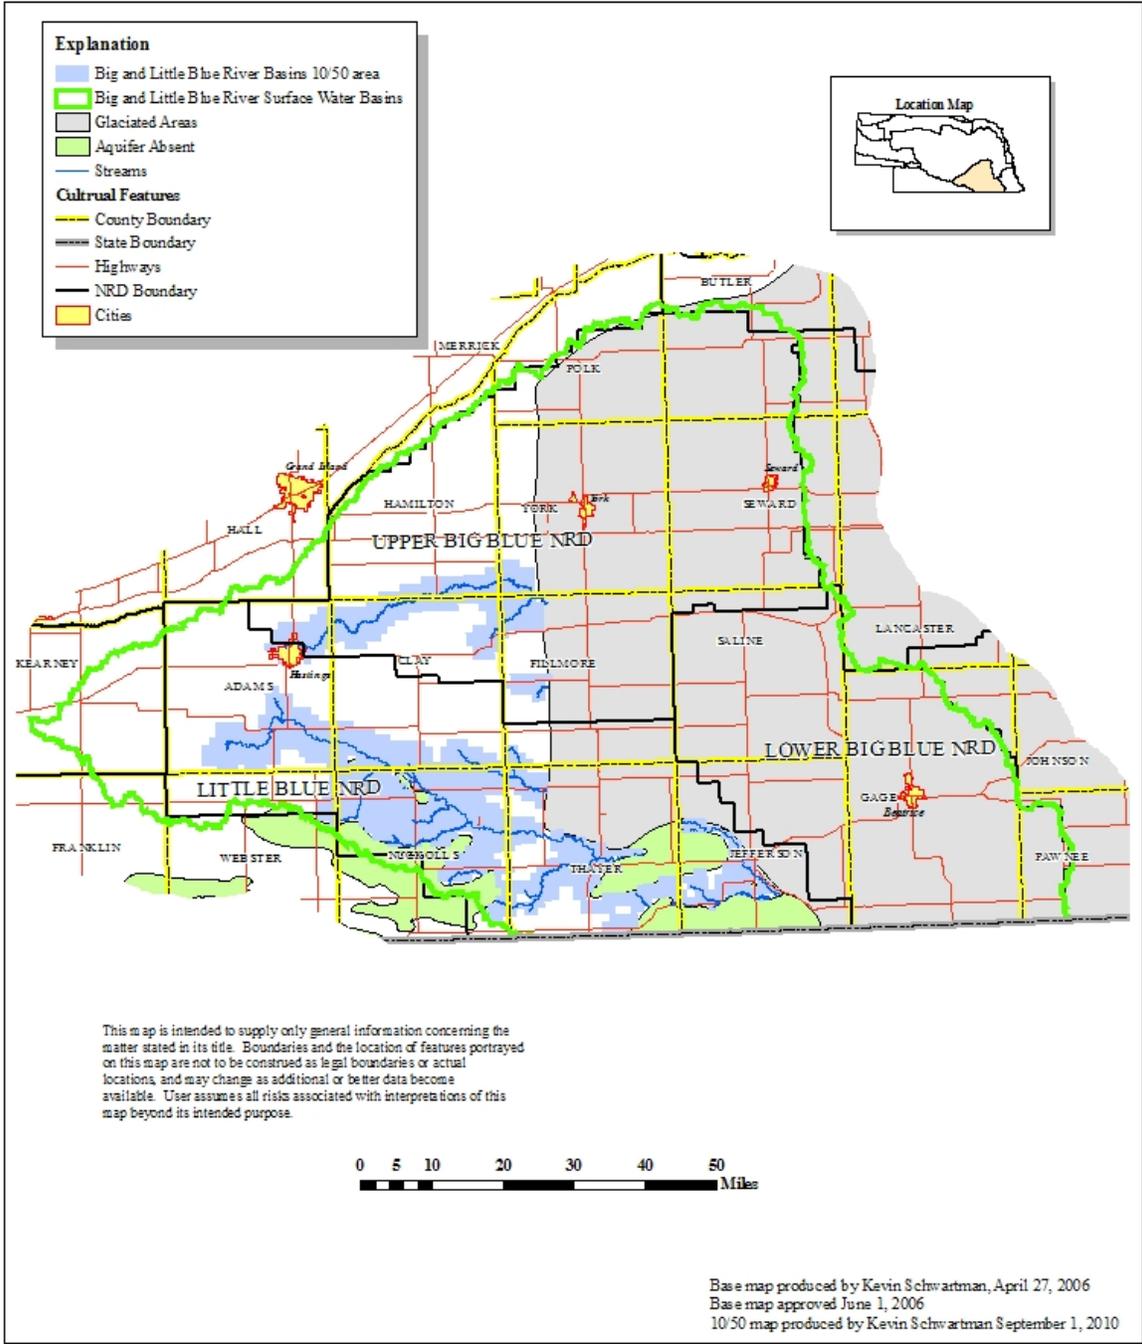

Figure 5-6. 10/50 area for the Blue River Basins.

5.5 Net Corn Crop Irrigation Requirement

Figure 5-7 is a map of the net corn crop irrigation requirement (NCCIR) for the Blue River Basins (DNR, 2005). The greatest NCCIR of a junior surface water appropriation in the Big Blue River Basin is 9.0 inches, and the greatest NCCIR in the Little Blue River Basin is 9.7 inches. To assess the number of days required for diversion, a surface water diversion rate equal to 1 cfs per 70 acres, a downtime of ten percent, and an irrigation efficiency of 80% were assumed. Based on these assumptions, the junior surface water appropriation in the Big Blue River Basin would need 23.9 days annually to divert 65% of the NCCIR and 31.3 days to divert 85% of the NCCIR. The junior surface water appropriation in the Little Blue River Basin will need 25.8 days annually to divert 65% of the NCCIR and 33.7 days to divert 85% of the NCCIR.

5.7 Evaluation of Current Development

5.7.1 Current Water Supply

The current water supply is estimated by using the previous twenty years (1990-2009) of surface water administration. The results of the analyses conducted for the Big Blue River Basin and Little Blue River Basin, respectively, are shown in tables 5-3 and 5-4. The results indicate that the current surface water supply in the Big Blue River Basin provides an average of at least 54.5 days available for diversion between July 1 and August 31 and 145.3 days available for diversion between May 1 and September 30 (table 5-5). The current surface water supply in the Little Blue River Basin provides an average of at least 54.7 days available for diversion between July 1 and August 31 and 143.2 days available for diversion between May 1 and September 30 (table 5-6).

Table 5-3. Estimate of the current number of days surface water is available for diversion in the Big Blue River Basin.

July 1 – August 31 (65% Requirement)	25.7	54.7 or greater (at least 29.0 days above the requirement)
May 1 – September 30 (85% Requirement)	33.6	143.2 (109.6 days above the requirement)

5.7.2 Long-Term Water Supply

In order to complete the long-term evaluation of surface water supplies, a future twenty-year water supply for the basins must be estimated. The basins’ water sources are precipitation, which runs off as direct streamflow and infiltrates into the ground to discharge as baseflow, and groundwater movement into the basins, which discharges as baseflow. Using methodology

published in the *Journal of Hydrology* (Wen and Chen, 2005), a nonparametric Mann-Kendall trend test of the weighted average precipitation in the basins was completed. The analysis showed no statistically significant trend in precipitation ($P > 0.95$) over the past sixty years (figure 5-8). Data do not exist to test whether trends in groundwater movement into the basin have changed. Therefore, using the previous twenty years of streamflow data as the best estimate of the future surface water supply is reasonable.

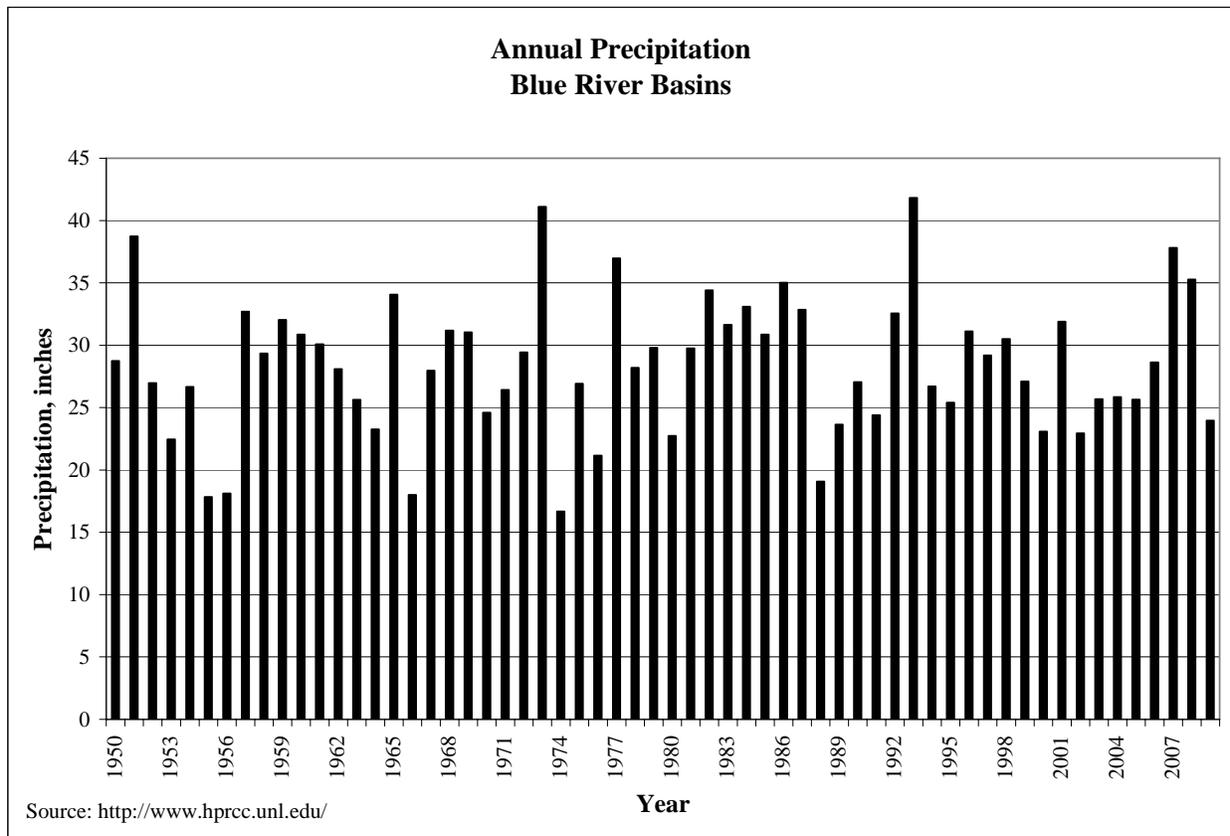

Figure 5-8. Annual precipitation, Blue River Basins.

5.7.3 Depletions Analysis

The future depletions due to current well development that could be expected to affect streamflow were estimated for the western portions of the Big Blue and Little Blue River Basins using Hunt methodology. The results estimate the future streamflow in the Big Blue River Basin to be depleted by 34 cfs in twenty-five years and flows in the Little Blue River Basin to be depleted by 25 cfs in twenty-five years.

5.7.4 Evaluation of Current Levels of Development against Future Water Supplies

The estimates of the twenty-year average number of days available for diversion are calculated by comparing the depleted future water supply with the flows necessary to satisfy the state line compact target flows. The results of the analyses are shown in tables 5-7 and 5-8. The results of the analyses as compared to the numbers of days surface water is required to be available to divert 65% and 85% of the NCCIR are detailed in tables 5-9 and 5-10. In all cases, the estimated long-term surface water supply, given current levels of development, is sufficient to satisfy the 65/85 rule.

Table 5-7. Estimate of days surface water is available for diversion in the Big Blue River Basin with current development and twenty-five-year lag impacts.

May 1 – September 30 (85% Requirement)	33.6	136.8 (103.2 days above the requirement)

5.8 Evaluation of Predicted Future Development

Estimates of the number of high-capacity wells (wells pumping greater than 50 gpm) that would be completed over the next twenty-five years, if no new legal constraints on the construction of such wells were imposed, were calculated based on extrapolating the present-day rate of increase

in well development into the future (figures 5-9 and 5-10). The present-day rate of development is based on the linear trend of the previous ten years of development in the basins. Based on the analysis of the past ten years of development, the rate of increase in high-capacity wells is estimated to be 77 wells per year in the Big Blue River Basin and 129 wells per year in the Little Blue River Basin.

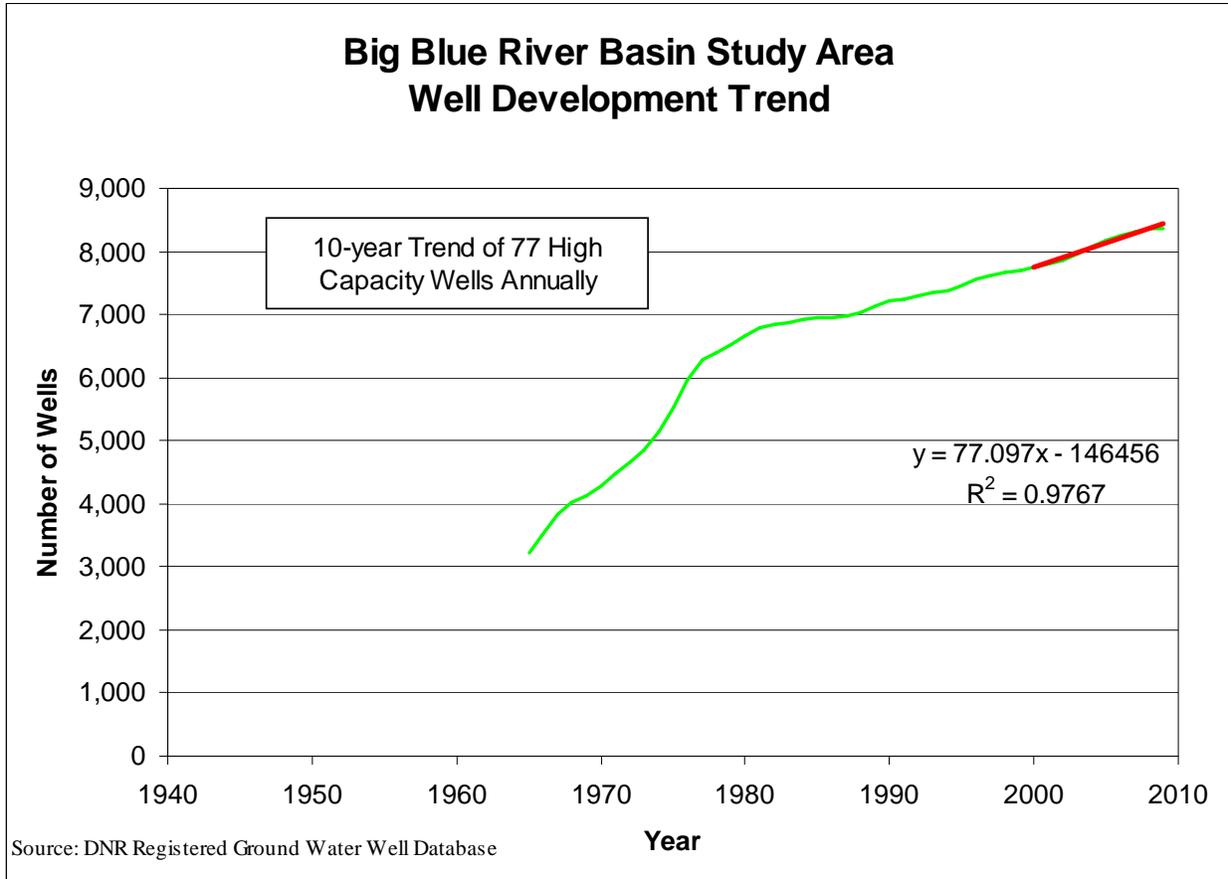

Figure 5-9. High capacity well development, western portion of Big Blue River Basin.

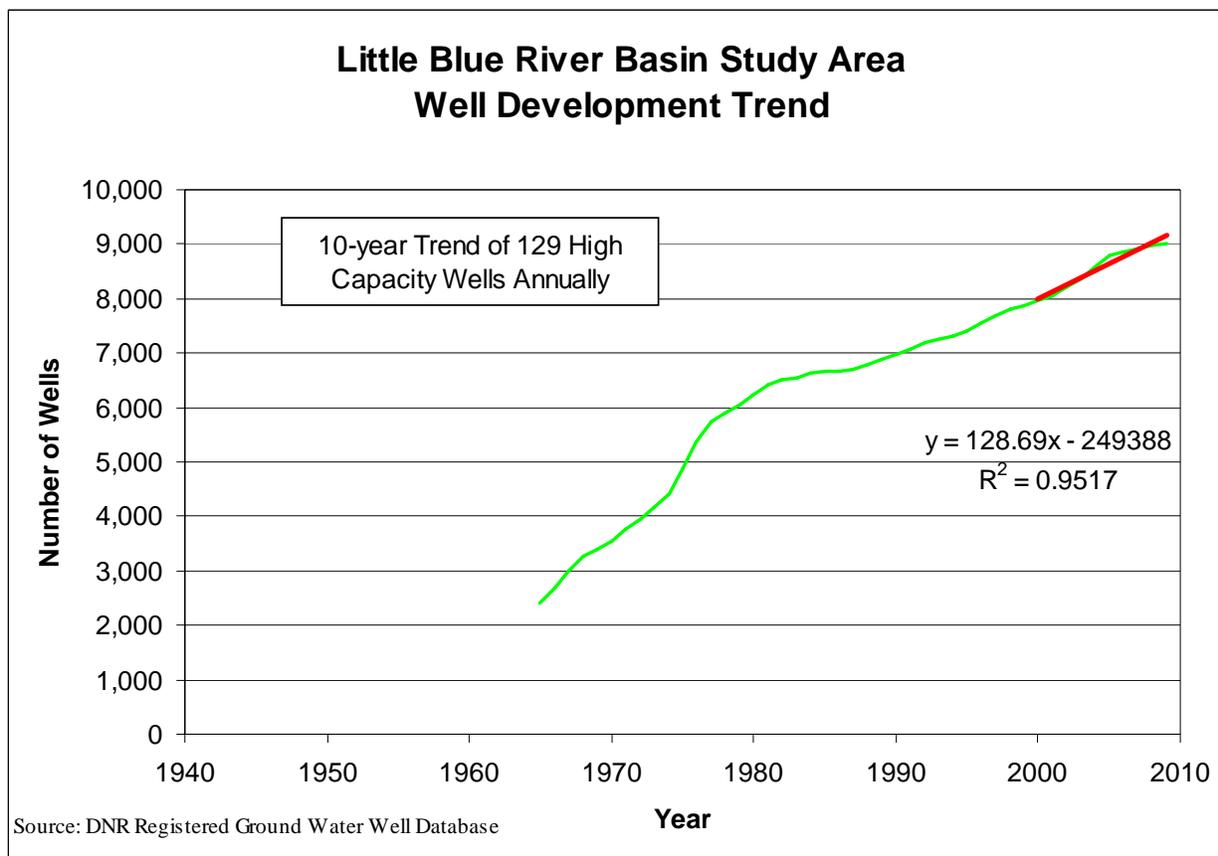

Figure 5-10. High capacity well development, western portion of Little Blue River Basin.

The future depletions due to current and future well development that could be expected to affect streamflow in the basin were estimated using an analytical methodology (Hunt, 1999). The results estimate the streamflow in the Big Blue River Basin will be depleted by an additional 1 cfs in ten years, 1cfs in fifteen years, 2 cfs in twenty years, and 4 cfs in twenty-five years due to potential future development. The results estimate the future streamflow in the Little Blue River Basin will be depleted by 3 cfs in ten years, 6 cfs in fifteen years, 10 cfs in twenty years, and 14 cfs in twenty-five years due to potential future development.

The estimate of the twenty-year average number of days surface water is available for diversion with additional future development is calculated by comparing the future lag-adjusted flow with the flows necessary to satisfy the state line compact flow targets. The results of the analyses are shown in tables 5-11 and 5-12. The results of the analyses as compared to the numbers of days surface water is required to be available to divert 65% and 85% of the NCCIR are detailed in

tables 5-13 and 5-14. The results indicate that, based on current information, the Department's conclusion that the basin is not fully appropriated would not change if no additional constraints are placed on future development of surface water and groundwater in the basin.

5.9 Sufficiency to Avoid Noncompliance

The State of Nebraska is a signatory member of the Kansas – Nebraska Big Blue River Compact (Compact). The purposes of the Compact are to promote interstate comity, to achieve an equitable apportionment of the waters of the Big Blue River Basin, to encourage continuation of

the active pollution-abatement programs in each of the two states, and to seek further reduction in pollution of the waters of the Big Blue River Basin.

The Compact sets state line flow targets from May 1 through September 30. The state line targets, measured in cubic feet of water per second, are shown in table 5-15. If the flow targets are not met, then the State of Nebraska is required to take the following actions:

1. Limit surface water diversions by natural flow appropriators to their decreed appropriations;
2. Close natural flow appropriators with priority dates junior to November 1, 1968, in accordance with the doctrine of priority;
3. Ensure that no illegal surface water diversions are taking place; and
4. Regulate wells installed after November 1, 1968, within the alluvium and valley side terrace deposits downstream of Turkey Creek in the Big Blue River Basin and downstream of Walnut Creek in the Little Blue River Basin, unless the Compact Administration determines that such regulation would not yield any measurable increase in flows at the state line gage.

For the present time, the Compact Administration has found that the regulation of those wells will not yield measurable increases in flow at the state line.

Table 5-15. State line flow targets for the Blue River Basins.

Month	Big Blue River Target Flow	Little Blue River Target Flow
May	45 cfs	45 cfs
June	45 cfs	45 cfs
July	80 cfs	75 cfs
August	90 cfs	80 cfs
September	65 cfs	60 cfs

As long as Nebraska administers surface and groundwater in compliance with the Compact, decreased streamflow, in and of itself, will not cause Nebraska to be in noncompliance; therefore, any depletion would not cause Nebraska to be in noncompliance. Decreased

streamflows could, however, increase the number of times the state would have to administer water to remain in compliance, thereby reducing the number of days available for junior irrigators to divert.

5.10 Groundwater Recharge Sufficiency

The streamflow is sufficient to sustain over the long term the beneficial uses from wells constructed in aquifers dependent on recharge from the stream, as explained in Appendix G.

5.11 Current Studies being Conducted to Assist with Future Analysis

A groundwater model developed for the Big Blue and Little Blue River Basins was reviewed by the Department in the spring 2009. The Department met with the Upper Big Blue NRD to inform them of shortcomings in the model. The model is currently being redeveloped for resubmission to the Department at which time it will be determined if the model is appropriate for use in determining the extent of the 10/50 area for the Big Blue and Little Blue Basins. Future efforts may be made to refine this model to estimate lag impacts from wells within the basins.

5.12 Relevant Data Provided by Interested Parties

The Department published a request for relevant data from interested parties for this year's evaluation on September 7, 2010 (see Appendix B for affidavit). The Department did not receive any such information.

5.13 Conclusions

Based on the analysis of the sufficiency of the long-term surface water supply in the Blue River Basins, the Department has reached a preliminary conclusion that the basins are not fully appropriated. The Department has also determined that, if no additional legal constraints are imposed on future development of hydrologically connected surface water and groundwater and reasonable projections are made about the extent and location of future development, this preliminary conclusion would not change to a conclusion that the basin is fully appropriated, based on current information.

The analysis of lag effects of current development for areas in the western portion of the Big Blue River Basin indicates a reduction in streamflows of 34 cfs in twenty-five years. The analysis of lag effects of current development for areas in the western portion of the Little Blue River Basin indicates a reduction in streamflows of 25 cfs in twenty-five years. It was not possible to calculate the lag effects of current development for areas in the eastern portions of the basins due to the glaciated nature of the area and the fact that the principal aquifer is absent or very thin (CSD, 2005).

The analysis of the impacts of potential future development in the western portion of the Big Blue River Basin based on current development trends indicates an additional reduction in streamflows of 4 cfs in twenty-five years. The analysis of the impacts of potential future development in the western portion of the Little Blue River Basin based on current development trends indicates an additional reduction in streamflows of 14 cfs in twenty-five years. The potential impacts of future development in the eastern portions of the basins were not evaluated at this time due to the glaciated nature of the area and the fact that the principal aquifer is absent or very thin (CSD, 2005).
